NONLINEAR MODEL SIMULATION OF SHIP MOTION

NGUYEN VAN DAO

Institute of Mechanics NCSR Vietnam

SUMMARY. Nonlinear model simulation of coupling between heave - roll and pitch - roll ship motions is considered by means of the asymptotic method of nonlinear mechanics. The purely vertical motion and vertical - angular motion and their stability are studied.

1. INTRODUCTION

The simulation of the coupling between heave roll and pitch roll motions of a ship running in a regular longitudinal or oblique sea has been studied by Tondl A. and Nabergoj R. [1]. The proposed model consists of a mass $M$ restrained by a linear elastic spring, which, in turn, carries a simple free oscillating pendulum made up of a mass $m$ attached to a hinged, weightless rod (Fig. 1). The system is forced to oscillate sinusoidally in the vertical direction by means of an external driver with constant amplitude $q$ and frequency $\omega$. The coupling between the vertical and angular oscillations is accomplished by connecting the two masses and the effect of the waves is simulated by means of external forcing.

In the present paper some results obtained by Tondl A. and Nabergoj R. [1, 2] will be extended for the case of a nonlinear elastic spring and nonlinear expansions of trigonometric functions.

2. MOTION EQUATIONS

Using the Lagrange equations for the system represented in Fig. 1 we have the following differential equations of motion:

\[(m + M)(\ddot{Z} + \ddot{\varphi}) + k_0 Z + \beta_0 \varphi^2 + k_0 \dot{Z} + m\ell(\dot{\varphi}\sin \varphi + \dot{\varphi}\cos \varphi) = 0,\]
\[m\ell^2 \dddot{\varphi} + C_0 \ddot{\varphi} + m\ell(g + \ddot{Z} + \ddot{\varphi})\sin \varphi = 0,\]

where $Z = x - u$ is the relative vertical displacement of the mass $M$, $x$ is the vertical displacement of the mass $M$ from its static position of equilibrium, $u = q\cos \omega t$ is the vertical displacement of the base of the spring - mass system, $\varphi$ is the angular displacement of the pendulum, $k_0$ and $\beta_0$ are the linear and nonlinear characteristics of the spring respectively, $\ell$ is the length of the rod,
$h_0$ and $C_0$ are the damping coefficients of the linear and angular motions, respectively, $g$ is the gravity acceleration and an overdot denotes a derivative with respect to time $t$.

By introducing the notations

$$\begin{align*}
w &= \frac{Z}{\ell}, \quad \eta = \frac{\omega}{\omega_0}, \quad \omega_0 = \sqrt{\frac{g}{\ell}}, \quad \zeta = \frac{C_0}{\omega_0 \ell^2}, \\
h &= \frac{h_0}{\omega_0(m + M)}, \quad k^2 = \frac{k_0}{\omega_0^2(m + M)}, \quad \beta = \frac{\beta \ell^2}{\omega_0^2(m + M)}, \\
\mu &= \frac{m}{m + M}, \quad \sigma = \frac{\eta}{\ell}, \quad \tau = \omega_0 t,
\end{align*}$$

and supposing that the damping forces and the ratios $\frac{\eta}{\ell} = \sigma, \frac{m}{m + M} = \mu$ are small, and limiting by considering small vibrations of coordinates, so that $w^3, \varphi^3, \varphi \varphi''', \varphi''^2, \varphi w''$ are small, we have the following equations of motion:

$$\begin{align*}
w'' + k^2 w &= -\epsilon f(w, w', \varphi, \varphi', \varphi'') + s^2 \ldots, \\
\varphi'' + \varphi &= \epsilon \Phi(w'', \varphi, \varphi') + s^2 \ldots,
\end{align*}$$

where a prime denotes a derivative with respect to the dimensionless time $\tau$,

$$\begin{align*}
f &= -\sigma \eta^2 \cos \eta \tau + h w' + \beta w^3 + \mu (\varphi \varphi'' + \varphi''^2), \\
\Phi &= -c \varphi' + \frac{\varphi''^2}{6} - \varphi w'' + \sigma \eta^2 \varphi \cos \eta \tau
\end{align*}$$

and $\epsilon$ is a small dimensionless positive parameter that is used as a book keeping device and will be set equal to unity in the final results. The case $\beta = 0, \sin \varphi \approx \varphi, \cos \varphi \approx 1$ has been examined in [1, 2].

3. APPROXIMATE SOLUTION

Let us consider the resonant region determined by

$$\begin{align*}
k^2 &= \eta^2 - \epsilon \Gamma, \\
\eta^2 &= 4(1 + \epsilon \Delta),
\end{align*}$$

where $\Gamma$ and $\Delta$ are detuning parameters. Using in equations (2.3) the transformation into new amplitude and phase variables $R, \theta, \alpha, \psi$ by means of the formulae

$$\begin{align*}
w &= R \cos \xi, \quad w' &= -R \eta \sin \xi, \quad \xi = \eta \tau + \theta, \\
\varphi &= \alpha \cos \alpha, \quad \varphi' &= -\frac{1}{2} \alpha \eta \sin \alpha, \quad \alpha = \frac{1}{2} \eta \tau + \psi,
\end{align*}$$

we have:

$$\begin{align*}
\eta R' &= \epsilon (f - \Gamma w) \sin \xi, \quad \eta \alpha' = -2 \epsilon (\Phi + \Delta \varphi) \sin \alpha, \\
R \eta \varphi' &= \epsilon (f - \Gamma w) \cos \xi, \quad \eta \alpha \psi' = -2 \epsilon (\Phi + \Delta \varphi) \cos \alpha.
\end{align*}$$

These equations are in the standard form for which the averaging technique of nonlinear mechanics [3] can be used. So, in the first approximation one can replace (3.3) by the following averaged equations:
\[ R' = \frac{\varepsilon}{2} [h R + \sigma \eta \sin \theta + \frac{1}{4} \mu \eta a^2 \sin(\theta - 2\psi)], \]

\[ R \eta' = \frac{\varepsilon}{2} [\Gamma R - \frac{3}{4} \beta R^3 + \sigma \eta^2 \cos \theta + \frac{1}{4} \mu \eta a^2 \cos(\theta - 2\psi)], \]

\[ a' = \frac{\varepsilon}{2} [c + \sigma \eta \sin \psi - R \eta \sin(\theta - 2\psi)], \]

\[ \alpha \eta \psi' = \frac{\varepsilon}{2} [2 \Delta \alpha + \frac{1}{4} \sigma \eta^2 \cos 2\psi + R \eta^2 \alpha \cos(\theta - 2\psi)]. \]  

(3.4)

4. PURELY VERTICAL SHIP MOTION

A stationary semi-trivial solution of equations (3.4) is

\[ a = 0, \quad \psi = \psi_0, \quad R = R_0, \quad \theta = \theta_0, \]  

(4.1)

where \( \psi_0 \) is an arbitrary constant and \( R_0, \theta_0 \) are constants satisfying the relations

\[ hR_0 + \sigma \eta \sin \delta_0 = 0, \]

\[ \Gamma R_0 - \frac{3}{4} \beta R^3_0 + \sigma \eta^2 \cos \delta_0 = 0. \]  

(4.2)

This solution corresponds to the vertical motion of the ship, while its angular motion remains unexcited.

Eliminating the phase \( \theta_0 \) from (4.2) we obtain an equation which defines the admissible values of the amplitude \( R_0 \) as a function of the excitation frequency \( \eta \):

\[ W(R_0^2, \eta^2) = 0, \]  

(4.3)

here

\[ W(R_0^2, \eta^2) = R_0^2 \left( h^2 \eta^2 + \left( \Gamma - \frac{3}{4} \beta R_0^2 \right)^2 \right) - \sigma^2 \eta^4, \]

\[ \varepsilon \Gamma = \eta^2 - k^2. \]  

(4.4)

This relationship can be expressed approximately as

\[ \eta^2 = k^2 + \frac{3}{4} \varepsilon \beta R_0^2 \pm \sqrt{\frac{\sigma^2 k^2}{R_0^2} - k^2}, \]  

(4.5)

and is plotted in Fig. 2 for the parameters \( k = 2, \ h = 10^{-1}, \ \sigma = 4.5 \cdot 10^{-2}, \ \beta = 0 \) (curve 1) and \( \beta = 1 \) (curve 2). With very small values of \( \sigma \), the amplitude \( R_0 \) is almost a small constant: \( R_0^2 \approx k^2 \sigma^2/h^2 \).

To study the stability of the semi-trivial solution (4.1) one lets

\[ a = \delta a, \quad \psi = \psi_0 + \delta \psi, \quad R = R_0 + \delta R, \quad \theta = \theta_0 + \delta \theta. \]

The following variational equations will be obtained

\[ \frac{d}{dt} (\delta R) = -\frac{\varepsilon}{2} [h \delta R + \sigma \eta \cos \theta_0 \delta \theta], \]

\[ R_0 \frac{d}{dt} (\delta \theta) = \frac{\varepsilon}{2} [(\Gamma - \frac{9}{4} \beta R_0^2) \delta R - \sigma \eta^2 \sin \theta_0 \delta \theta], \]

\[ \frac{d}{dt} (\delta a) = \frac{\varepsilon}{2} [c + \sigma \eta \sin \psi_0 - \eta R_0 \sin(\theta_0 - 2\psi_0)] \delta a, \]

\[ 0 = [2 \Delta + \sigma \eta^2 \cos 2\psi_0 + \eta^2 R_0 \cos(\theta_0 - 2\psi_0)] \delta a, \]  

(4.6)
From the first two equations of (4.6) and from (4.2) and (4.3) one can find after a short calculation the stability condition

\[
\frac{\partial w}{\partial R_0} > 0
\]

which is imposed upon the resonant curve [see heavy lines in Fig.2] of the vertical motion of the ship.

The boundary of the instability region for the appearance of a parametric resonance of angular ship motion is determined from the last two equations of (4.6) as

\[
c + \sigma \eta \sin 2\psi_0 - \eta R_0 \sin(\phi_0 - 2\psi_0) = 0, \\
2\Delta + \sigma \eta^2 \cos 2\psi_0 + \eta^2 R_0 \cos(\phi_0 - 2\psi_0) = 0.
\]

Eliminating the phases \(\psi_0, \phi_0\) gives

\[
\eta^2 \epsilon^2 + 4\Delta^2 = \eta^4 (\epsilon^2 + R_0^2) + 2\eta^2 R_0^3 \left(\frac{3}{4} \epsilon R_0^2 - 1\right), \\
\epsilon \Delta = \frac{1}{4} \eta^2 - 1,
\]

or

\[
\eta^2 = 4 \pm 2 \epsilon \sqrt{k^2 (\epsilon^2 + R_0^2) - c^2 + 2 R_0^3 \left(\frac{k^2 - \eta^2}{\epsilon} + \frac{3}{4} \epsilon R_0^2\right)}
\]

where \(R_0\) satisfies equation (4.3). The relation (4.9) is plotted in Fig.3 for the case \(\beta = 1\), \(c = 10^{-1}\), \(h = 10^{-1}\), and \(k = 1.9\) (curve 1), \(k = 2\) (curve 2), \(k = 2.1\) (curve 3). These curves are approximately parabolic and the instability region is located above the parabola (see shaded region in Fig.3). For sufficiently small values of the excitation \(\sigma\), the semi-trivial solution remains stable. Corresponding to every instability region there exists a “threshold” \(\sigma = \sigma_0\) which must be exceeded before instability can occur.

Taking into account curve 2 in Fig.3, one can see that for \(\sigma = 4.5 \cdot 10^{-2}\) and \(2.75 \leq \eta^2 \leq 4.9\) the parametric vibration of angular motion may occur. So, in the interval \(2.75 \leq \eta^2 \leq 4.9\) the ship motion will not be characterized only by the resonant curve in Fig.2. Outside the mentioned interval the angular motion of the ship will be zero and the ship motion is characterized only by
the resonant curve in Fig. 2. In the last case the amplitude of ship vibration will be small and almost constant. Therefore, for the case considered, the purely vertical motion (without angular motion) occurs only with small amplitude. The strong vertical motion will be accompanied by the angular one.

Fig. 2

5. COUPLING BETWEEN VERTICAL AND ANGULAR MOTIONS

The non-trivial stationary solution of equations (3.4) with \( \alpha \neq 0, R \neq 0 \) is determined from the relation:

\[
\begin{align*}
\sigma \eta^2 \sin \theta + \frac{1}{4} \mu \eta^2 \alpha^2 \sin(\theta - 2\psi) &= -h \eta R, \\
\sigma \eta^2 \cos \theta + \frac{1}{4} \mu \eta^2 \alpha^2 \cos(\theta - 2\psi) &= \left( \frac{3}{4} R^2 - \Gamma \right) R, \\
\sigma \eta^2 \sin 2\psi - R \eta^2 \sin(\theta - 2\psi) &= -c \eta, \\
\sigma \eta^2 \cos 2\psi + R \eta^2 \cos(\theta - 2\psi) &= -\left( 2\Delta + \frac{1}{4} \alpha^2 \right).
\end{align*}
\]

This solution corresponds to the simultaneous vertical and angular motions of the ship. Eliminating the phase variables in these equations we obtain the following expression giving the dependence of the amplitudes of vibration \( \alpha, R \) on the frequency \( \eta \) of the exciting force:

\[
\eta^2 (c^2 - h^2 R^2) + \left[ 2\Delta + \frac{1}{4} \alpha^2 - \frac{1}{4} \mu \eta^2 \alpha^2 \right]^2 = R^2 \left( \eta^2 \Gamma + \frac{3}{4} \beta R^2 \right)^2.
\]

This relationship is plotted in Fig. 4 for the case \( \beta = 1, k = 2, h = c = 0.1 \) and \( \mu = 0.05 \). From Fig. 4 it is seen that, increasing \( \eta \) from the resonant value (\( \eta = 2 \)) and keeping constant the amplitude of vertical motion, the amplitude of angular ship vibration (\( \alpha \)) decreases, and at a constant value of the excitation frequency (\( \eta \)) the amplitudes of vertical and angular ship vibrations either increase or decrease simultaneously.
CONCLUSION

The nonlinear model simulation of coupling between vertical and angular ship motions has been considered. The nonlinear terms in the motion equations have essential influence on both the shape of the response curve and the instability region in comparison with the linear equations [1, 2]. The condition for the appearance of a purely vertical vibration of the ship has been derived. In the case considered this vibration occurs only with small amplitude and the strong vertical ship vibration is always accompanied by angular motion. The stationary simultaneous vertical and angular motions of the ship have been studied too.
